System Design Assessment: Meridian + Jarvis

eigi.ai FDE intern hiring · Round 2 · Candidate brief

How to use this doc

This is round 2 of the eigi.ai forward-deployed engineer intern hiring: a 48-hour, design-only take-home. You design a company brain on top of a messy, multi-system supply chain business, working from a context pack too large to read without AI. No code is graded. We judge how you use AI, whether your output is specific or generic, how you understand the business, and how well you explain your thinking.

- Sections 1 to 3 describe the company, its systems and Jarvis.
- Sections 4 to 7 are your task, the ground rules, how we judge your AI use, and how to submit.

This brief is based on a real problem from one of our client engagements. Meridian Supply Chain mirrors the shape of that business (seller platform, two-warehouse WMS, partners portal, catalog, several Postgres databases, and an AI company brain called Jarvis). The problems are real. Your submission is used only to evaluate you for this role.

1. The company: Meridian Supply Chain

Meridian Supply Chain (MSC) is a 25-person company that buys sealed collectibles (trading card boxes, coins and bullion) from independent sellers, checks them in a warehouse, and resells them in bulk to business buyers. It makes money on the spread between what it pays sellers and what partners pay it.

There are three groups of people in the business:

- **Members (sellers).** About 6,000 individuals who sell products to MSC. They pick items from a buy list with fixed prices ("pre-quotes"), ship them to a warehouse, and get paid by ACH, PayPal or wallet credit once the items pass inspection. They live in a Discord community where they open cashout and support tickets.
- **Partners (buyers).** About 400 businesses (hobby shops, distributors, live sellers) that buy from MSC through the partners portal: they browse the catalog, request quotes, place orders, receive invoices and pay.
- **The internal team.** Staff, contractors and developers across operations, warehouse, finance, sales and engineering. Everyone uses AI tools daily: Claude Code, Codex, ChatGPT, Claude desktop, Gemini CLI and Cursor.

Two warehouses, East and West, run on one warehouse management system. Products are organized brand → set → product (for example: a card game brand → a named expansion set → a specific sealed box). Prices move daily, so MSC also publishes a public market page

with sealed-product prices and an index.

How MSC works: goods move from sellers to partners through the warehouse; money flows back.

The seller site, warehouse and portal each run on their own database, and none of them share IDs.

2. The systems today

MSC runs on five systems built by different people at different times. With this brief you get a context pack: full dumps of the three databases over 90 days, a finance export, API specs, every company note and SOP, 30 days of the team's AI session logs, and the first version's usage logs. That is roughly 2 million tokens, deliberately more than a person or a single AI chat can read in two days. Much of what matters about the business is only visible there.

System	Used by	Database
Seller site	Members, ops	seller_db
Warehouse management (WMS)	Warehouse floor, ops	wms_db
Partners portal (catalog, quotes, orders, public market prices)	Partners, all staff	portal_db
Accounting	Finance	QuickBooks

Around these sit Discord, Google Workspace, Slack, Linear and GitHub.

Context pack: [download link]

3. Jarvis: the company brain

> "When anyone uses any LLM, I want it to auto-read from and auto-append to the memory. Use fewer tokens, have a shared brain where anybody can ask anything about MSC. Eventually I want it to find issues, come up with ideas, and think of smarter ways to run the company." — the founder

Jarvis has three jobs: give every teammate's AI a shared memory of the company, answer any business question from live data, and spot problems and ideas before the founder does. A rough first version exists. Almost nobody uses it. Its notes and logs are in the context pack.

Questions the founder wants answered:

- "How many packages did the warehouse receive yesterday?"
- "Am I really making money right now?"
- "What did [teammate] ship this week?"
- "What should I worry about today?"

4. Your task

Design Jarvis for MSC, along with whatever the rest of the platform must change for it to work. We do not want code. We want to see how well you understand this business, which problems you go after, and how you reason about the software.

Two rules make this hard:

- **Everything must come from the pack.** Every claim about MSC (a problem, a number, a pattern in how the team works) must point to evidence in the context pack. Advice that could apply to any company scores zero.
- **The pack is too big to read.** You will need AI to work through it, and you will need to check what it tells you.

Submit:

- **Three founder questions, answered from the pack:** "How many packages did the warehouse receive yesterday?", "Am I really making money right now?" and "What should I worry about today?" Give the answer, the evidence, and every assumption you had to make.
- **A design document** in any format. Diagrams expected. No set outline. It must handle the requirement change described in section 7.
- **Your AI log** (section 6), including one "AI got it wrong" case written up in full: what the AI claimed, how you caught it, and the evidence from the pack that proved it wrong.
- **Your raw AI transcripts** (section 6).

5. Ground rules from the founder

These are fixed. If you think one is wrong, or two of them conflict, say so and show how you would handle it.

- Internal team only for now. Partners and members may come later.
- Business numbers come from the live systems. They are not copied into memory.
- The founder's personal notes stay private to the founder.
- Every teammate's AI sessions feed Jarvis automatically, with no approval step.
- Sensitive data (pay, bank details, HR) is restricted.
- Small budget: one modest EU server and the existing AI accounts. AI spend should go down, not up.

6. How we judge your AI use

Use any models, agents, sub-agents and tools you want. This cannot be done well in 48 hours without heavy AI use. We are not judging whether you used AI; we are judging how.

We look at:

- How you break the problem down, and what you hand to AI versus think through yourself.
- What context you give it. A pasted brief gets a generic answer.
- How you verify. Where you checked an AI claim against the pack, and where you overruled it.
- How hard you push it. Making it attack your design, compare options, find what you missed.
- What you can explain. You should be able to defend everything you submit without the AI in the room.

Include:

- An AI log: the key steps, what you asked, what you kept or threw away and why, and at least 3 times the AI was wrong or shallow.
- Your raw transcripts, unedited (exports or share links). The log and the transcripts must match.

In round 3 you will defend and change your design live in front of us.

7. Timeline and submission

You have 48 hours from when you receive this brief. The deadline is **7 November 2026, 23:59 IST**.

To submit:

- Create a Google Drive folder named FullName_eigi_FDE_Assessment and put all four deliverables in it: founder answers, design document, AI log, and raw transcripts.
- Set the folder and every file to "Anyone with the link can view". If we cannot open a link, we cannot score it.
- Submit the folder link and each deliverable link through one form: https://forms.gle/hhmr7aGvTdPLWBME6

Late submissions are not read.

The best candidates come in for a 1-day in-person round 3.
